

Abstract

The purpose of this study was to determine whether there were differences in the prevalence of self-reported depression between men and women who had been exposed to violence during childhood and adulthood. Data from the National Longitudinal Study of Adolescent Health (*N = 9,800*) were used to examine the association between exposure to violence and self-reported depression among adolescents. Results showed that exposure to violence during childhood and adulthood was associated with higher rates of self-reported depression. The association between exposure to violence and self-reported depression was stronger for women than for men. These findings suggest that exposure to violence during childhood and adulthood may have a greater impact on the mental health of women than men.
